$X = 0$ is the CENTRE LINE

E THE DATUM, AND THE TABLE

(0, 0) IS THE TABLE CENTRE: the SEAM LINE crossing the LONG CENTRE LINE.

In sheet-1/2 canvas coordinates that is $x = 901.7$, $y = 1815.32$. Every number on this sheet is that point subtracted, and every number carries its sign: +X toward the $x = 1803.4$ long edge, +Y toward the $y = 3630.64$ end.

THE SEAM LINE IS FOUR LINES AT ONCE.

system_model makes SEAM_Y (1815.32) the canvas mid-length, the MIDDLE ARM ROW, the half-cage butt plane, and the line the seam bars straddle. Find the seam bars and you have found $Y = 0$ without a tape.

THE MODEL CENTRES THE CANVAS ON THE TABLE, both ways.

The table body's centre is (+0.00, +0.00) from the canvas centre – the same two lines – and the table overhangs the canvas by 114.3 mm on all four sides.

Model table 2032.0 x 3859.24, X -1016.0 .. +1016.0, Y -1929.6 .. +1929.6. Its HEIGHT is the drawing's; its FOOTPRINT is ASSUMED — the cage's own inner span, because the original's 2.08 m table cannot carry this canvas.

AND THE TAPE DISAGREES ABOUT THE LENGTH: 416.6 cm measured = 4165.6 = two batted half-frames, against the model's assumed 3859.24 — +306.36 mm. THE TABLE ENDS ON THIS SHEET ARE THE TAPE'S, Y = +2082.8, drawn dashed; the model's assumed footprint is drawn solid inside them.

HOW TO USE IT AT THE RIG.

Snap one line down the middle of the paper and one across at the seam bars. Hook the tape on the crossing and read outward; the sign says which way you went. Panel A's ordinate ticks are all off those two lines and nothing else.

NOTHING HERE IS A SURVEY.

It is the model re-datumed — the same steel sheets 1 and 2 draw from the canvas corner. Where a tape and the model disagree, panel C says so and the model is not edited to match.

C MEASURED BY HAND 2026-09-16 vs THE MODEL

what a tape read	tape	model	tape - model
clear gap, the two INNER posts of a row	214	216.2	-2.20
outer width of ONE post pair	396	393.8	+2.20
J1 axis -> outside face, SHORT side	156	171.75	-15.75
J1 axis -> outside face, LONG side	240	222.05	+17.95
=> J1 axis offset inside the pair (derived)	42	25.15	+16.85
table length, end to end	4166	4165.6	+0.40

ONE ROW IS A REAL DISAGREEMENT AND IT IS THE PLATE OFFSET. Three of the five readings are within 2.5 mm of the model, which is a tape on 3-in extrusion. The two axis-to-face readings are not: they put the J1 axis 42 mm off the centre of its own post pair where the model puts it 25.15 mm off — and that 25.15 is the ONE number on the whole mount that was never measured (open item 1, PLATE OFFSET DIRECTION). RE-MEASURE IT with a straight edge laid across the base flange and the two post faces, not by eye off the plate edge.

D STRUT FACE SCHEDULE

every face of all four struts in a row, as a SIGNED X off the centre line

LEFT column 13 / 31 / 2

j1 axis			-305.00
strut 1 faces	-476.75		-400.55
strut 1 centre			-438.65
strut 2 faces	-159.15		-82.95
strut 2 centre			-121.05
plate edges	-392.76		-166.94
plate centre			-279.85

RIGHT column 17 / 71 / 97

j1 axis		+305.00
strut 1 faces	+133.25	+209.45
strut 1 centre		+171.35
strut 2 faces	+450.85	+527.05
strut 2 centre		+488.95
plate edges	+217.24	+443.06
plate centre		+330.15

THE TWO COLUMNS ARE NOT MIRRORED.

Every plate on the rig is offset 25.15 mm in +X from its own J1 axis (uniform clocking, BUILD_SHEET section 3), so the SHORT 171.75 face is on the -X side of BOTH columns: toward the centre on the right column and away from it on the left. Read the schedule, not the symmetry.

REV A — SUPERSEDES THE 1435 / 1525 DROP POSTS of old milling 8020 layout.* — that grid datum read the drawing's 233,7 cm (FLOOR to top of cage) as if it were measured from the paper. DO NOT CUT FROM THE OLD SHEET.
CENTRE-DATUM SET — sheets 3 and 4 dimension the SAME model from the TABLE CENTRE, signed. They do not supersede sheets 1 and 2; those are set-out from the canvas corner, these are for a tape at the built rig.
